Let  $k$  be a number field,  $\mathbb{A}$  its adèle ring and  $G$  a connected reductive group over  $k$ .

## 1 The Topology of Local Fields

Given a global field and a place  $\nu$  we get a local field  $k_\nu$  an induced metric topology. It has the properties:

- All are locally compact
- For all but finitely many  $\nu$ ,  $k_\nu$  is compact.
- $k_\nu, k_\nu^*$  are both totally disconnected

## 2 The Topology on $\mathbb{A}$

We have defined the adèles as a topological product, hence the topology is already specified here we give only properties of this topology. Recall that we identify  $k$  with its image in  $\mathbb{A}$  under the inclusion map

$$\alpha \mapsto (\alpha)_\nu$$

i.e. the constant sequence. With this in mind the adelic topology has the properties:

- Locally compact and Hausdorff
- $k$  is a discrete set in  $\mathbb{A}$
- $k$  is closed in  $\mathbb{A}$
- $\mathbb{A}/k$  is compact in the quotient topology
- For any finite set of places  $S$   $k$  is dense in

$$\prod'_{\nu \notin S} k_\nu$$

the removal of just one place takes us from discrete to dense.

### 3 The Topology on $G(\mathbb{Q})$

Throughout  $X, Y, Z$  are affine schemes of finite type over  $R$  where  $R$  is a topological ring.

We first identify  $X \cong \text{Spec}(R[t_1, \dots, t_n]/I)$  then  $X(R)$  is naturally the set of points in  $R^n$  on which the polynomials in  $I$  all vanish. We then give it the subspace topology.

**Theorem.** *This is the unique topology on the  $R$  points of  $X, Y, Z$  that is*

- *Functorial: If  $X \rightarrow Y$  is a morphism of schemes over  $R$  then  $X(R) \rightarrow Y(R)$  is continuous*
- *Compatible with pullbacks:  $(X \times_Y Z)(R) \cong X(R) \times_{Y(R)} Z(R)$ ; homeomorphic topological spaces.*
- *Compatible with embeddings: A closed immersion  $X \hookrightarrow Y$  is sent to a topological embedding  $X(R) \hookrightarrow Y(R)$*
- *Compatible with  $R$  points:  $\text{Spec}(R[t])(R) \cong R$  topologically.*

Moreover under this topology  $X(R)$  forms a topological group, and if  $R$  is locally compact, or Hausdorff so is  $X(R)$ .

### 4 The Topology on $G(\mathbb{A})$

[Con12] is the reference. Let  $X$  be an affine scheme of finite type over a global field  $F$ . Then  $X \cong \text{Spec}(F[t_1, \dots, t_n]/I)$  and  $X(F)$  is naturally the set of points in  $F^n$  on which the polynomials in  $I$  all vanish.  $X(\mathbb{A})$  is identified with the subset of  $\mathbb{A}^n$  where  $f : \mathbb{A}^n \rightarrow \mathbb{A}$  in  $I$  vanish. We give this the subspace topology.
